

Speak Like A Mathematician:

solve a right triangle:

inverse trig ratios:

Inverse Trigonometric Ratios

$$\theta = \sin^{-1}(\text{opposite} / \text{hypotenuse}) \quad \cdot \quad \theta = \cos^{-1}(\text{adjacent} / \text{hypotenuse}) \quad \cdot \quad \theta = \tan^{-1}(\text{opposite} / \text{adjacent})$$

Plan for solving a triangle: find the third side with the _____ Theorem (or a trig ratio), find one acute angle with an _____ ratio, then subtract from _____° for the other.

Example 1 - Two Legs Known

In $\triangle PQR$ at the right, the right angle is at R, $PR = 12$ and $QR = 9$. Round decimals to the nearest tenth.

- a) Find PQ.
- b) Find $m\angle P$.
- c) Find $m\angle Q$.

Example 2 - Hypotenuse and a Leg

The right triangle at the right has hypotenuse 26 and a leg of 10.

- Find the third side.
- Find both acute angles.

Example 3 - An Angle and the Hypotenuse

The triangle at the right has a 34° angle and hypotenuse 20.

- Find both legs.
- Find the other acute angle.

Example 4 - An Angle and a Leg

The triangle at the right has a 58° angle whose ADJACENT leg is 7.

- Find the other leg and the hypotenuse.
- Find the remaining angle, then list all six parts.
