

Compass-and-Straightedge Constructions

A construction uses only a compass and a straightedge — no rulers, no protractors, no measuring. Every construction in this packet is justified by a theorem from Chapter 3.

Construction 1 - A Line Through P Parallel to Line m

Given line m and a point P not on m , construct the line through P that is parallel to m .

- Step 1.** Draw line m and label a point P not on m . Choose any point Q on line m and draw line QP .
- Step 2.** Place the compass at Q . Draw an arc that crosses line m at A and line QP at B .
- Step 3.** Keeping the same compass setting, place the compass at P and draw an arc that crosses line QP at C .
- Step 4.** Open the compass to the distance AB . From C , draw an arc that crosses the arc from Step 3 at D . Draw line PD . This line is parallel to m .

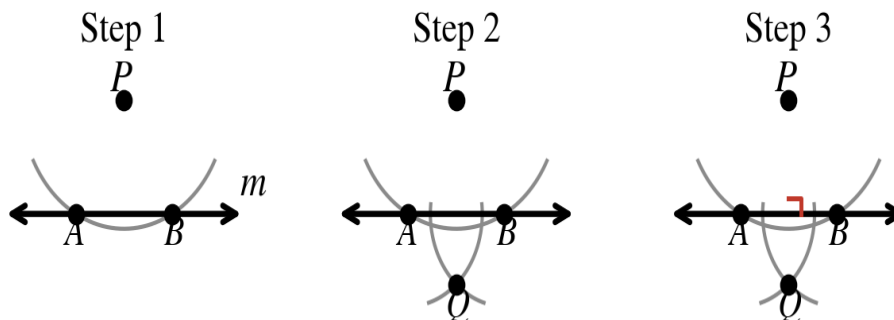

Why it works: Steps 2–4 copy the angle at Q to the same position at P . That makes $\angle DPQ$ and $\angle AQP$ a pair of congruent corresponding angles, so $PD \parallel m$ by the Corresponding Angles Converse.

Construction 2 - A Perpendicular from a Point NOT on the Line

Given line m and a point P not on m , construct the line through P perpendicular to m .

- Step 1.** Place the compass at P . Open it wide enough that the arc crosses line m twice. Label the intersections A and B .
- Step 2.** Place the compass at A and draw an arc below line m . Keeping the same setting, place the compass at B and draw a second arc. Label the intersection of the two arcs Q .
- Step 3.** Draw line PQ . This line is perpendicular to line m .

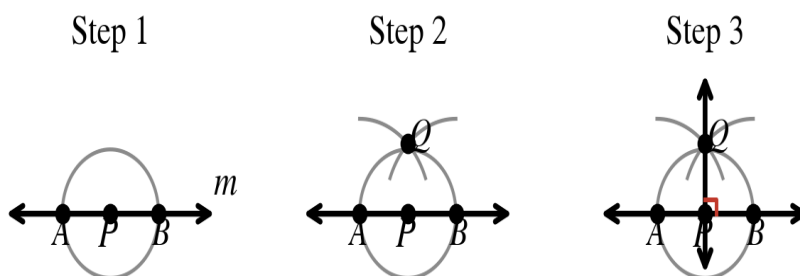

Why it works: P and Q are each the same distance from A and from B , so both lie on the perpendicular bisector of $\overline{AB}$ — and that line is perpendicular to m .

Construction 3 - A Perpendicular from a Point ON the Line

Given line m and a point P on m , construct the line through P perpendicular to m .

- Step 1.** Place the compass at P and draw an arc that crosses line m on both sides. Label the intersections A and B .
- Step 2.** Open the compass wider than PA . From A , draw an arc above the line; from B , draw a second arc with the same setting. Label their intersection Q .
- Step 3.** Draw line PQ . This line is perpendicular to line m at P .

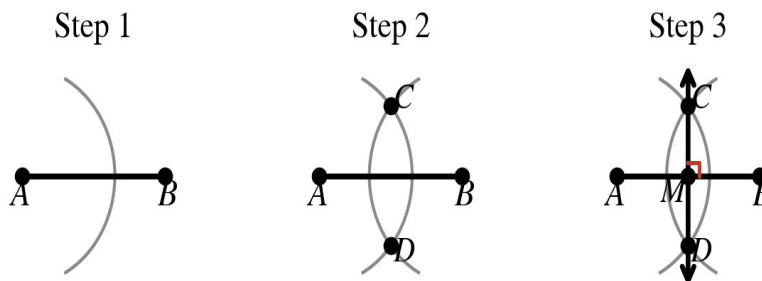

Why it works: $PA = PB$ by Step 1 and $QA = QB$ by Step 2, so P and Q both lie on the perpendicular bisector of $\overline{AB}$.

Construction 4 - The Perpendicular Bisector of a Segment

Given segment $\overline{AB}$, construct its perpendicular bisector and locate the midpoint M .

- Step 1.** Place the compass at A and open it to MORE than half of AB . Draw an arc above and below the segment.
- Step 2.** Keeping the same compass setting, place the compass at B and draw a second pair of arcs. Label the two intersections C and D .
- Step 3.** Draw line CD . It is perpendicular to $\overline{AB}$ and it passes through the midpoint M , so $AM = MB$.

Why it works: C and D are each equidistant from A and B . Two points that are equidistant from the endpoints determine the perpendicular bisector of the segment.

Name: _____

Now You Try

Use a compass and straightedge on a separate sheet. Show all construction arcs — do not erase them.

1. Draw a line j and a point R above it. Construct the line through R parallel to j . Check it: a pair of corresponding angles should measure the same.
2. Draw a segment about 4 inches long. Construct its perpendicular bisector. Both halves should measure the same, and the angle at the midpoint should be 90° .
3. Draw an acute triangle. Construct the perpendicular from one vertex to the opposite side. This segment is called an **altitude**.
4. Challenge: use Construction 3 twice to construct a square. Start with a segment $\overline{AB}$, then construct perpendiculars at A and at B.

Work space — show your arcs.
